JHT project team:

I finally finished updating the input file for the TC uncertainty model. I put the gzipped file nnfit_vlist.dat.gz in our project folder in the data subfolder. I also put a readme_vlist.txt file in that same directory that provides a summary of the variables in the data file.

I made a number of changes to the file as follows:

- 1) I changed the longitude convention to 0 to 360.
- 2) I added the NHC official intensity and track forecasts in terms of the deviation from the consensus. There are a lot more missing values for those because sometimes they run the models before they make an official forecast.
- 3) I added 5 more storm environment variables, as follows.
 - T200 - 200 hPa temperature
 - D200 - 200 hPa divergence
 - RHMD - mid-level relative humidity
 - SPDX - the eastward component of the storm motion vector
 - SPDY - the northward component of the storm motion vector

I thought the forecast storm motion vector components might be useful for predicting track uncertainty and the others might help with the intensity forecast uncertainty, but it would be worth trying them all for both track and intensity.

Below is the link to our project folder.

Let me know if you have any questions.

Thanks,

Mark
