Based on the feedback from the previous version, I made a few more changes to the nnfit_vlist.dat file and related readme file. The new versions are on project drive. I removed the old ones and put the date in the new files names.

The only difference in the nnfit_vlist.dat file is that I changed the definitions of the NHC official forecast variables based on Libby's suggestion. The variables OFDV, OFDX and OFDY are now the differences between the best track and official forecasts (best track - official) for the intensity, longitude (converted to distance east) and latitude (converted to a distance north). These are defined the same way as OBDV, OBDX and OBDY which are the differences between the best track and consensus forecast (best track - consensus). Thus, we can just swap the OB values with the OF values for the dependent variable input if we want to predict the NHC errors instead of the consensus model errors (but checking for missing OF values). That is more logical, which was the motivation for Libby's suggestion.

I also changed the readme file to be consistent with the new vlist file, added the definitions of two vlist variables I accidentally left out before, and expanded the description of the difference variables to include the definition of what is subtracted from what.

Also, it sounds like we are making a lot of progress on the fortran code and the GPCE work. I am finalizing a new proposal this week and traveling to Miami the week after that, but will try to schedule our next technical meeting the week of Nov 14th or Nov 21st, depending on who is available.

Let me know if you have further questions.

Thanks,

Mark
